The 22-year-old, who is currently on a season-long loan at Magpies boss Rafa Benitez's side, has been watched on several occasions at St James' Park. Hernandez spent time on loan at Chelsea, where he scored 15 goals in 61 appearances, before moving to City in January 2018. In the summer, he made the switch to St James' Park permanently, where he has scored three goals in 30 appearances. Albion's interest means Hernandez will have to impress at the Old Trafford club if he wants to be loaned out to a Premier League rival. Despite Magpies boss Benitez refusing to publicly sing the striker's praises, Hernandez has admitted that he is disappointed with the number of chances he has been given. "I am just waiting to be given more chances to score. I am on the pitch, I am waiting to be given more chances," he was

In this study, a coupled-mode based software RSPMatch was used to match the recorded. ad hoc to the dynamic model, and find the parameters of the. rsmatch software to match recorded signals.This invention relates to light microscopes and, more particularly, to electron microscope column condensers for the conversion of an electron beam to an optical image. A typical optical light microscope produces a magnified image of a sample by utilizing lenses and adjusting the path of light between the sample and the lenses. Such light microscopes are capable of viewing of objects to a resolution on the order of tenths of a micron. An electron microscope, in contrast, produces magnified images by utilizing electron beams and means for focusing the electron beams on the samples. The latter means includes condensers which have been the subject of considerable design and development work. In order to produce a magnified image of a sample on a viewing screen, the electron beam is focused by first of all a condenser which directs the electron beam onto a primary electron detector. The beam which passes through the condenser is subsequently directed to a secondary electron detector. In such a system, if the primary and the secondary detectors are located in the same plane, the image of the sample will be upright. Accordingly, the usual procedure is to separate the primary and the secondary detectors by a very thin aperture in the center thereof, with the two detectors located diametrically opposite each other. As a result of this separation, the image that is formed in the viewing screen is inverted, that is to say, the image is upside down. The inverted image is typically corrected by hand by inverting the sample and re-erecting it using the electron beam. In other
