official site for more information. Currently, there are many applications for unmanned ground vehicles (UGV) in military and nonmilitary applications. UGVs have the advantages of lower

cost and faster deployment than manned vehicles.

However, UGVs have several disadvantages.

They are limited in mobility, are vulnerable to damage and in performance due to

numerous problems associated with the transmission of power and the balance of the vehicle. Unlike wheeled vehicles, which can be readily steered on flat surfaces, UGVs are often steered on rough terrain.

These vehicles are much more susceptible to damage when struck with sticks or similar objects. Further, these vehicles are not always as mobile or versatile as some other vehicles. Additionally, the cost of

UGVs are high. This is due in part to the transmission and the complexity of control systems which have to incorporate substantial vehicle control. Further, the high cost of fuel also contributes to the high

cost of UGVs. There are a number of solutions to the problems associated with UGVs. One type of solution is to increase the mobility of the UGV by utilizing the power of a powerful source in order to increase the

vehicle's speed. A transmission, hydraulic pump, and hydraulic motor are commonly used for this purpose. Other types of solutions are to use military UGV's or tanks to supply power to more conventional

vehicles. However, although these UGVs have improved mobility, they are limited because they require a dedicated transmission, lack maneuverability, and require substantial maintenance. Therefore,

there is a need for a low cost, non-military UGV with improved maneuverability, speed and performance, which is also capable of transmitting power to a second, separate vehicle. (ABP) and mean arterial

pressure (MAP). A significant (p\ 6d1f23a050
